Stavropol State Medical University, Russian Federation

The problem of developing purulent-septic complications after neonatal surgery remains unsolved [1]. Many researchers believe the development of such complications affects the mortality in the given group of patients [2].

Despite the lack of common approaches to the early diagnosis and treatment of septic complications, some authors believe the mechanism of development is closely connected with the violation of cell membrane permeability and the subsequent translocation of intestinal flora through the intestinal membrane [3, 4]. This is also favored by the age characteristics of the newborn with immaturity of the immune and barrier systems.

In recent years, interest has increased in antimicrobial peptides (AMPs) and bactericidal/permeability increasing protein (BPI) in particular, which is localized in the vacuoles of granulocytes [5]. Its concentration in serum increases in inflammatory diseases and allergic reactions. There are studies confirming its role in the destruction of bacterial cell membrane polysaccharides in vitro and in animal experiments. A high concentration of peptide in the blood is required to achieve a bactericidal effect [6]. A literature review revealed no publications considering this peptide as a marker of intestinal wall damage in neonates.

The aim of this study was to investigate the influence of bactericidal protein (BPI) on the development of complications after abdominal surgery in infants with congenital anomalies of the gastrointestinal tract.

Material and Methods. This was a prospective non-randomized controlled study that included 24 infants who were treated in the intensive care unit of Children’s Regional Clinical Hospital from 2010 to 2011. The inclusion criteria were as follows: 1) the presence of congenital anomalies of the gastrointestinal tract (GIT) that were diagnosed prenatally and 2) a surgical procedure in the first days after the diagnosis of surgical disease. The control points in the study were the number and type of septic complications and duration of mechanical ventilation. The exclusion criteria were multiple congenital anomalies and the child’s death during the first day after surgery.

All of the children belonged to a group at high risk for postoperative septic complications, and at least one of the following factors was present: 1) the late arrival of newborns on the stage of specialized care, 2) transportation failure to comply with the standards by non-specialized vehicles, 3) long-term (over 15 min) hypothermia.

The children were divided into two groups. Group 1 (n=10) included newborns with inflammatory complications after surgery, and group 2 (n=14) included children who had no complications after surgery. The control group consisted of healthy newborns (n=20) after a normal physiological birth. The structure of the GIT congenital anomalies is presented in Table. All of the children underwent surgical correction of the congenital anomaly on the first or second day after diagnosis. Patients in both groups at all stages of care received complex intensive care in compliance with generally accepted principles of treatment in neonatology, pediatric surgery and anaesthesiology and intensive care.

Table

Characteristics of surgical pathology in newborns

The vital signs of all the children were monitored via ECG monitoring of systolic, diastolic and mean arterial pressure by non-invasive method and tissue oxygen saturation (\(\text{SaO}_2\)). The hematocrit was controlled before and after the injection of solutions. The following blood parameters were determined: total protein, electrolytes (Na, Ca, K), sugar, creatinine, urea and liver enzymes (ALT, AST, alkaline phosphatase). The blood plasma BPI level was determined in the children preoperatively and on the 1st, 3rd, 7th and 14th postoperative days. The level of BPI «BCM Diagnostics» was determined using an ELISA.

The analysis of the reliability of the differences between the groups was carried out by methods of variation statistics using the licensed computer program Statistica 6.0. The data were reviewed using the Shapiro-Wilk method to choose an adequate method of statistical analysis. This result (\(p=0.36\)) suggests the need for nonparametric statistical methods. We used the Wilcoxon test to analyze the statistical reliability between the groups. The critical significance level (\(p\)) for verification of the statistical hypotheses in this study was set at 0.05. The median (Me) interquartile range was 25 – 75 %.

**Results.** In group 1, the post-operative complications included anastomotic obstruction (\(n=2\)), leakage at the anastomosis and prolonged adynamic ileus (\(n=3\)), and sepsis or pneumonia (\(n=5\)).

The level of BPI in group 1 was 3.33 (2.74–4.51) ng/ml preoperatively and 4.49 (1.48–5.7) ng/ml on the first postoperative day. After 3 days, the BPI level increased markedly to 15.75 (3.32–50.5) ng/ml and then decreased gradually on day 7 to 4.425 (3.38–55.4) ng/ml and to 3.23 (0.01–30.9) ng/ml 14 days after the operation (Fig. 1).

In group 2, the BPI level was 10.5 (3.35–19.05) ng/ml preoperatively. On the 1st postoperative day, it decreased to 2.755 (1.835–6.545) ng/ml, and on postoperative day 3, the level remained stable at 2.915 (1.37–55.5) ng/ml. The BPI level increased on the 7th postoperative day to 33.45 (21.7–45.2) ng/ml and remained unchanged by the 14th postoperative day at 34.5 (34.5–34.5) ng/ml (Fig. 2).

**Discussion.** The production of AMPs is commonly considered a primitive mechanism of immunity. The antimicrobial activity of saliva largely depends on histidine-rich AMPs known as histatins. Many more AMPs and AMP-like proteins exist and exhibit various functions apart from their antimicrobial properties. The AMP-like protein of the neutrophil granule content, bactericidal/permeability increasing protein (BPI), is able to permeabilize bacterial membranes and function as an opsonin [7]. BPI stored in azurophil granules is a major constituent of neutrophils (0.5 to 1 % of total protein) and is present in eosinophils in smaller amounts. The epithelial cells of the oral, gastrointestinal and female genital tracts produce BPI [8].

The potent and selective antibiotic and endotoxin-neutralizing properties of BPI manifest with nM concentrations of either the full-length BPI molecule or rBPI21 stimulated extensive preclinical and clinical testing of rBPI21. In a variety of animal models, recombinant human BPI (rBPI) and its amino-terminal derivate (rBPI21) were protective against lethal and sub-lethal challenges with Gram-negative bacteria and endotoxin [5]. Subsequent studies in humans, including studies in meningococcal sepsis, showed a significant protective effect of BPI, although it is not yet sufficient to be approved for clinical application. These studies strongly suggested that BPI can act *in vivo* to help resolve Gram-negative bacteria infections and endotoxin-induced inflammation [9].

In an open label, dose-escalation phase I/II trial, 26 pediatric patients with fulminant meningococcal sepsis were treated with rBPI21 administered

![Fig. 1. BPI dynamics in infants with inflammatory complications](image1)

![Fig. 2. BPI dynamics in newborns without inflammatory complications](image2)
intravenously. Only one of the patients (4 %) died, which favorably compared to a historical control group with 20 % mortality (11 of 54 patients). In a subsequent phase III, randomized, placebo-controlled trial, 190 patients received rBPI21 and 203 received placebo. The beneficial effect of rBPI21 could be confirmed. The reduction in mortality did not reach statistical significance, probably because the study was underpowered by an inappropriate design not taking into account the high mortality of patients in the time between recruitment and drug administration [10].

BPI can induce apoptosis in human vascular endothelial cells in vitro and inhibit their migration in a wound assay [11]. The amino-terminal part of BPI (rBPI21) inhibited ischemia-induced or diabetes-induced neo-vascularization in the retina of mice, suggesting an antiangiogenic effect of BPI. It is conceivable that BPI could impair the vascular access of GNB by inhibiting neo-angiogenesis in settings where chronic neutrophilic inflammation prevails, e.g., in inflammatory bowel diseases [12].

**THE PROGNOSTIC VALUE OF BACTERICIDAL/PERMEABILITY-INCREASING PROTEIN IN INFANTS WITH CONGENITAL PATHOLOGY OF THE GASTROINTESTINAL TRACT**

Minaev S. V., Isaeva A. V., Tovkan E. A., Gudiev Ch. G., Timofeev S. I., Kachanov A. V., Romaneeva N. M.

The aim of this study was to investigate the influence of bactericidal/permeability-increasing protein (BPI) on the development of complications after abdominal surgery in infants.

We investigated the intestinal hormone levels in the blood before and after surgery (1, 3, 7 and 14 postoperative days) in infants with congenital intestinal obstruction anomaly and atresia. The children were divided into group 1 (N=10), which included newborns with inflammatory complications after the surgery, and group 2 (N=14), which included newborns without inflammatory complications. Twenty infants without operative treatment formed the control group. The level of BPI was determined by ELISA.

BPI is a pluripotent protein located in neutrophils and tissue that likely plays a pivotal role in host defense against microorganisms and endotoxin by means of its antibiotic and endotoxin-neutralizing and disposing functions. Further studies are needed to understand how BPI expression is controlled in different tissue cells. A better understanding of the regulation of BPI expression in epithelial and connective tissue settings may suggest novel approaches to increase the local antibacterial and anti-inflammatory properties and may be especially useful in newborns with congenital GI anomalies.

**Conclusion**

1. The high level of BPI after surgery in infants with a congenital anomaly on the first postoperative day is a favorable prognostic sign regarding the disease outcome.

2. Initially, low levels of BPI in the serum of a child in conjunction with increased levels on the third day can serve as a marker of an unfavorable outcome, but further research is required in this area.
SLEEVE GASTRECTOMY FOR MORBID OBESITY – REGIONAL EXPERIENCE

Khatsiev B. B., Kuzminov A. N.

Stavropol State Medical University, Russian Federation

Morbidity obesity is the actual issue for healthcare of developed countries. In Russia 51 % of men and 58 % of women are either overweight or obese[1]. Obesity is closely associated with type 2 diabetes mellitus, arterial hypertension and other diseases [2].

Meta-analysis of numerous randomized studies had shown that bariatric surgery can induce not only weight-loss, but also is more effective in management of type 2 diabetes mellitus than conservative treatment, including long-term period [3].

Sleeve gastrectomy is one of the most recent widely recognized bariatric procedures. While it is not completely clear whether it should be used as primary procedure, number of sleeve gastrectomies constantly increases [4]. In 2012 sleeve gastrectomy became the most common bariatric operation in Russia, shifting adjustable gastric banding to the second position [5].

Objective of research. This study summarizes result of three-year experience of sleeve gastrectomy at regional clinics of Stavropol kray. The results will contribute to the regional strategy of treatment of morbid obesity and diabetes mellitus. This paper also aims to reveal information on bariatric surgery to regional surgeons, endocrinologists and general practitioners.

Material and Methods. We have been performing sleeve gastrectomies since December 2010. 116 operations have been made by the March 2014; 24 (21 %) patients are males, 92 (79 %) – females. Mean age of patients is 38.0±9.8 years, minimal age – 15, maximal – 62. Average body mass index (BMI) is 46.5±7.3 kg/m², minimal BMI – 34.3 kg/m², maximal – 72.7 kg/m². Maximal patient weight was 215 kg.

Insulin resistance or glucose intolerance pre-operatively were find out in 16 (13,8 %) patients, 12 (13,8 %) patients suffered type 2 diabetes mellitus with oral therapy, 2 (1.7 %) more patients were on insulin treatment.

All procedures were carried put under general endotracheal anesthesia that was augmented in 12 (10.3 %) cases with peridural anesthesia. In 19 % of cases other operations were performed simultaneously – 16 (13.8 %) cholecystectomies, 4 (3.4 %) hernia repairs, 1 (0.8 %) ovarian cyst removal and 1 (0.8 %) adhesiolysis.

2 operations were performed by laparotomy (due to multiple previous laparotomies), 1 operation commenced as laparoscopic, but was converted to hand-assisted with usage of minimally invasive system «Dextrus» due to enormous size of left hepatic
